## Sato-Tate in dimension 1

Let $E / \mathbb{Q}$ be an elliptic curve, which we can write in the form

$$
y^{2}=x^{3}+a x+b,
$$

and let $p$ be a prime of good reduction $\left(4 a^{3}+27 b^{2} \not \equiv 0 \bmod p\right)$.
The number of $\mathbb{F}_{p}$-points on the reduction $E_{p}$ of $E$ modulo $p$ is

$$
\# E_{p}\left(\mathbb{F}_{p}\right)=p+1-t_{p}
$$

where the trace of Frobenius $t_{p}$ is an integer in $[-2 \sqrt{p}, 2 \sqrt{p}]$.
We are interested in the limiting distribution of $x_{p}=-t_{p} / \sqrt{p} \in[-2,2]$, as $p$ varies over primes of good reduction.

## Example: $y^{2}=x^{3}+x+1$

## Sato-Tate distributions in dimension 1

1. Typical case (no CM)

Elliptic curves $E / \mathbb{Q}$ w/o CM have the semi-circular trace distribution. (This is also known for $E / k$, where $k$ is a totally real number field). [Taylor et al.]

## 2. Exceptional cases (CM)

Elliptic curves $E / k$ with CM have one of two distinct trace distributions, depending on whether $k$ contains the CM field or not.
[classical]

## Sato-Tate groups in dimension 1

The Sato-Tate group of $E$ is a closed subgroup $G$ of $\mathrm{SU}(2)=\mathrm{USp}(2)$ derived from the $\ell$-adic Galois representation attached to $E$.

The refined Sato-Tate conjecture implies that the normalized trace distribution of $E$ converges to the distribution of traces in $G$ given by the Haar measure.

| $G$ | $G / G^{0}$ | $E$ | $k$ | $\mathrm{E}\left[a_{1}^{0}\right], \mathrm{E}\left[a_{1}^{2}\right], \mathrm{E}\left[a_{1}^{4}\right] \ldots$ |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{U}(1)$ | $\mathrm{C}_{1}$ | $y^{2}=x^{3}+1$ | $\mathbb{Q}(\sqrt{-3})$ | $1,2,6,20,70,252, \ldots$ |
| $N(\mathrm{U}(1))$ | $\mathrm{C}_{2}$ | $y^{2}=x^{3}+1$ | $\mathbb{Q}$ | $1,1,3,10,35,126, \ldots$ |
| $\mathrm{SU}(2)$ | $\mathrm{C}_{1}$ | $y^{2}=x^{3}+x+1$ | $\mathbb{Q}$ | $1,1,2,5,14,42, \ldots$ |

In dimension 1 there are three possible Sato-Tate groups, two of which arise for elliptic curves defined over $\mathbb{Q}$.

## Zeta functions and $L$-polynomials

For a smooth projective curve $C / \mathbb{Q}$ of genus $g$ and each prime $p$ of good redution for $C$ we have the zeta function

$$
Z\left(C_{p} / \mathbb{F}_{p} ; T\right):=\exp \left(\sum_{k=1}^{\infty} N_{k} T^{k} / k\right),
$$

where $N_{k}=\# C_{p}\left(\mathbb{F}_{p^{k}}\right)$. This is a rational function of the form

$$
Z\left(C_{p} / \mathbb{F}_{p} ; T\right)=\frac{L_{p}(T)}{(1-T)(1-p T)},
$$

where $L_{p}(T)$ is an integer polynomial of degree $2 g$.
For $g=1$ we have $L_{p}(t)=p T^{2}+c_{1} T+1$, and for $g=2$,

$$
L_{p}(T)=p^{2} T^{4}+c_{1} p T^{3}+c_{2} T^{2}+c_{1} T+1 .
$$

## Normalized $L$-polynomials

The normalized polynomial

$$
\bar{L}_{p}(T):=L_{p}(T / \sqrt{p})=\sum_{i=0}^{2 g} a_{i} T^{i} \in \mathbb{R}[T]
$$

is monic, reciprocal ( $a_{i}=a_{2 g-i}$ ), and unitary (roots on the unit circle).
The coefficients $a_{i}$ necessarily satisfy $\left|a_{i}\right| \leq\binom{ 2 g}{i}$.
We now consider the limiting distribution of $a_{1}, a_{2}, \ldots, a_{g}$ over all primes $p \leq N$ of good reduction, as $N \rightarrow \infty$.

In this talk we will focus primarily on the case $g=2$.

## Exceptional trace distributions of genus 2 curves $C / \mathbb{Q}$

## The Sato-Tate group

For each prime $\ell$ and abelian variety $A / k$, the action of $G_{k}:=\operatorname{Gal}(\bar{k} / k)$ on $V_{\ell}(A):=\left(\lim A\left[\ell^{n}\right]\right) \otimes \mathbb{Q}_{\ell}$ induces a Galois representation

$$
\rho_{\ell}: G_{k} \rightarrow \operatorname{Aut}_{\mathbb{Q}_{\ell}}\left(V_{\ell}(A)\right) \simeq \operatorname{GSp}_{2 g}\left(\mathbb{Q}_{\ell}\right) .
$$

Fixing an embedding $\iota: \mathbb{Q} \ell \hookrightarrow \mathbb{C}$, we now apply

$$
\operatorname{ker}\left(G_{k} \rightarrow \mathbb{Q}_{\ell}^{\times}\right) \xrightarrow{\rho_{\ell}} \mathrm{Sp}_{2 g}\left(\mathbb{Q}_{\ell}\right) \xrightarrow{\iota} \mathrm{Sp}_{2 g}(\mathbb{C}),
$$

and define $\mathrm{ST}_{A}$ to be a maximal compact subgroup of the image.
Conjecturally, $\mathrm{ST}_{A}$ does not depend on $\ell$ or $\iota$; this is known for $g \leq 3$.

## Definition [Serre]

$\mathrm{ST}_{A} \subseteq \mathrm{USp}(2 g)$ is the Sato-Tate group of $A$.

## The Sato-Tate conjecture

Let $s(\mathfrak{p})$ denote the conjugacy class of $\rho_{\ell}\left(\right.$ Frob $\left._{\mathfrak{p}}\right) / \sqrt{\|\mathfrak{p}\|} \in \mathrm{ST}_{A}$. Let $\mu_{\mathrm{ST}_{A}}$ denote the image of the Haar measure on $\operatorname{Conj}\left(\mathrm{ST}_{A}\right)$, which does not depend on the choice of $\ell$ or $\iota$.

## Conjecture

The conjugacy classes $s(\mathfrak{p})$ are equidistributed with respect to $\mu_{\text {ST }_{A}}$.

In particular, the distribution of $\bar{L}_{\mathfrak{p}}(T)$ matches the distribution of characteristic polynomials of random matrices in $\mathrm{ST}_{A}$.

We can test this numerically by comparing statistics of the coefficients $a_{1}, \ldots, a_{g}$ of $\bar{L}_{\mathfrak{p}}(T)$ over $\|\mathfrak{p}\| \leq N$ to the predictions given by $\mu_{\mathrm{ST}_{A}}$.

## The Sato-Tate axioms

The Sato-Tate axioms for abelian varieties (weight-1 motives):
(1) $G$ is closed subgroup of $\operatorname{USp}(2 g)$.
(2) Hodge condition: $G$ contains a Hodge circle ${ }^{1}$ whose conjugates generate a dense subset of $G$.
(3) Rationality condition: for each component $H$ of $G$ and each irreducible character $\chi$ of $\mathrm{GL}_{2 g}(\mathbb{C})$ we have $\mathrm{E}[\chi(\gamma): \gamma \in H] \in \mathbb{Z}$.

For any fixed $g$, the set of subgroups $G \subseteq \operatorname{USp}(2 g)$ that satisfy the Sato-Tate axioms is finite up to conjugacy.

[^0]

For any fixed $g$, the set of subgroups $G \subseteq \operatorname{USp}(2 g)$ that satisfy the Sato-Tate axioms is finite up to conjugacy.

## Theorem

For $g \leq 3$, the group $\mathrm{ST}_{A}$ satisfies the Sato-Tate axioms.
This is expected to hold for all $g$.
${ }^{1}$ An embedding $\theta: \mathrm{U}(1) \rightarrow G^{0}$ where $\theta(u)$ has eigenvalue $u$ with multiplicity $g$.

## Sato-Tate groups in dimension 2

## Theorem 1 [FKRS 2012]

Up to conjugacy, 55 subgroups of $\operatorname{USp}(4)$ satisfy the Sato-Tate axioms:

$$
\begin{aligned}
\mathrm{U}(1): & C_{1}, C_{2}, C_{3}, C_{4}, C_{6}, D_{2}, D_{3}, D_{4}, D_{6}, T, O, \\
& J\left(C_{1}\right), J\left(C_{2}\right), J\left(C_{3}\right), J\left(C_{4}\right), J\left(C_{6}\right), \\
& J\left(D_{2}\right), J\left(D_{3}\right), J\left(D_{4}\right), J\left(D_{6}\right), J(T), J(O), \\
& C_{2,1}, C_{4,1}, C_{6,1}, D_{2,1}, D_{3,2}, D_{4,1}, D_{4,2}, D_{6,1}, D_{6,2}, O_{1} \\
\mathrm{SU}(2): & E_{1}, E_{2}, E_{3}, E_{4}, E_{6}, J\left(E_{1}\right), J\left(E_{2}\right), J\left(E_{3}\right), J\left(E_{4}\right), J\left(E_{6}\right) \\
\mathrm{U}(1) \times \mathrm{U}(1): & F, F_{a}, F_{c}, F_{a, b}, F_{a b}, F_{a c}, F_{a b, c}, F_{a, b, c} \\
\mathrm{U}(1) \times \mathrm{SU}(2): & \mathrm{U}(1) \times \mathrm{SU}(2), N(\mathrm{U}(1) \times \mathrm{SU}(2)) \\
\mathrm{SU}(2) \times \mathrm{SU}(2): & \mathrm{SU}(2) \times \mathrm{SU}(2), N(\mathrm{SU}(2) \times \mathrm{SU}(2)) \\
\mathrm{USp}(4): & \mathrm{USp}(4)
\end{aligned}
$$

## Sato-Tate groups in dimension 2

## Theorem 1 [FKRS 2012]

Up to conjugacy, 55 subgroups of USp(4) satisfy the Sato-Tate axioms:

$$
\begin{aligned}
\mathrm{U}(1): & C_{1}, C_{2}, C_{3}, C_{4}, C_{6}, D_{2}, D_{3}, D_{4}, D_{6}, T, O, \\
& J\left(C_{1}\right), J\left(C_{2}\right), J\left(C_{3}\right), J\left(C_{4}\right), J\left(C_{6}\right), \\
& J\left(D_{2}\right), J\left(D_{3}\right), J\left(D_{4}\right), J\left(D_{6}\right), J(T), J(O), \\
& C_{2,1}, C_{4,1}, C_{6,1}, D_{2,1}, D_{3,2}, D_{4,1}, D_{4,2}, D_{6,1}, D_{6,2}, O_{1} \\
\mathrm{SU}(2): & E_{1}, E_{2}, E_{3}, E_{4}, E_{6}, J\left(E_{1}\right), J\left(E_{2}\right), J\left(E_{3}\right), J\left(E_{4}\right), J\left(E_{6}\right) \\
\mathrm{U}(1) \times \mathrm{U}(1): & F, F_{a}, F_{c}, F_{a, b}, F_{a b}, F_{a c}, F_{a b, c, c}, F_{a, b, c} \\
\mathrm{U}(1) \times \operatorname{SU}(2): & \mathrm{U}(1) \times \operatorname{SU}(2), N(\mathrm{U}(1) \times \operatorname{SU}(2)) \\
\mathrm{SU}(2) \times \operatorname{SU}(2): & \mathrm{SU}(2) \times \operatorname{SU}(2), N(\operatorname{SU}(2) \times \operatorname{SU}(2)) \\
\mathrm{USp}(4): & \mathrm{USp}(4)
\end{aligned}
$$

Of these, exactly 52 arise as $\mathrm{ST}_{A}$ for an abelian surface $A(34$ over $\mathbb{Q})$.

## Sato-Tate groups in dimension 2

## Theorem 1 [FKRS 2012]

Up to conjugacy, 55 subgroups of $\operatorname{USp}(4)$ satisfy the Sato-Tate axioms:

$$
\begin{aligned}
\mathrm{U}(1): & C_{1}, C_{2}, C_{3}, C_{4}, C_{6}, D_{2}, D_{3}, D_{4}, D_{6}, T, O, \\
& J\left(C_{1}\right), J\left(C_{2}\right), J\left(C_{3}\right), J\left(C_{4}\right), J\left(C_{6}\right), \\
& J\left(D_{2}\right), J\left(D_{3}\right), J\left(D_{4}\right), J\left(D_{6}\right), J(T), J(O), \\
& C_{2,1}, C_{4,1}, C_{6,1}, D_{2,1}, D_{3,2}, D_{4,1}, D_{4,2}, D_{6,1}, D_{6,2}, O_{1} \\
\mathrm{SU}(2): & E_{1}, E_{2}, E_{3}, E_{4}, E_{6}, J\left(E_{1}\right), J\left(E_{2}\right), J\left(E_{3}\right), J\left(E_{4}\right), J\left(E_{6}\right) \\
\mathrm{U}(1) \times \mathrm{U}(1): & F, F_{a}, F_{c}, F_{a, b}, F_{a b}, F_{a c}, F_{a b b, c, c}, F_{a, b, c} \\
\mathrm{U}(1) \times \mathrm{SU}(2): & \mathrm{U}(1) \times \operatorname{SU}(2), N(\mathrm{U}(1) \times \operatorname{SU}(2)) \\
\mathrm{SU}(2) \times \mathrm{SU}(2): & \mathrm{SU}(2) \times \operatorname{SU}(2), N(\mathrm{SU}(2) \times \operatorname{SU}(2)) \\
\mathrm{USp}(4): & \mathrm{USp}(4)
\end{aligned}
$$

Of these, exactly 52 arise as $\mathrm{ST}_{A}$ for an abelian surface $A(34$ over $\mathbb{Q})$.
This theorem says nothing about equidistribution, however this is now known in many special cases [FS 2012, Johansson 2013].

## Galois types

Let $A$ be an abelian variety defined over a number field $k$.
Let $K$ be the minimal extension of $k$ for which $\operatorname{End}\left(A_{K}\right)=\operatorname{End}\left(A_{\overline{\mathbb{Q}}}\right)$.
$\operatorname{Gal}(K / k)$ acts on the $\mathbb{R}$-algebra $\operatorname{End}\left(A_{K}\right)_{\mathbb{R}}=\operatorname{End}\left(A_{K}\right) \otimes_{\mathbb{Z}} \mathbb{R}$.

## Definition

The Galois type of $A$ is the isomorphism class of $\left[\operatorname{Gal}(K / k), \operatorname{End}\left(A_{K}\right)_{\mathbb{R}}\right]$, where $[G, E] \simeq\left[G^{\prime}, E^{\prime}\right]$ iff there are isomorphisms $G \simeq G^{\prime}$ and $E \simeq E^{\prime}$ that are compatible with the the Galois action.

Note: in several cases $G \simeq G^{\prime}$ and $E \simeq E^{\prime}$, but $[G, E] \nsucceq\left[G^{\prime}, E^{\prime}\right]$.

## Galois types and Sato-Tate groups in dimension 2

## Theorem 2 [FKRS 2012]

Up to conjugacy, the Sato-Tate group $G$ of an abelian surface $A$ is uniquely determined by its Galois type, and vice versa.

We also have $G / G^{0} \simeq \operatorname{Gal}(K / k)$, and $G^{0}$ is uniquely determined by the isomorphism class of $\operatorname{End}\left(A_{K}\right)_{\mathbb{R}}$, and vice versa:

$$
\begin{array}{rrrr}
\mathrm{U}(1) & \mathrm{M}_{2}(\mathbb{C}) & \mathrm{U}(1) \times \operatorname{SU}(2) & \mathbb{C} \times \mathbb{R} \\
\mathrm{SU}(2) & \mathrm{M}_{2}(\mathbb{R}) & \operatorname{SU}(2) \times \operatorname{SU}(2) & \mathbb{R} \times \mathbb{R} \\
\mathrm{U}(1) \times \mathrm{U}(1) & \mathbb{C} \times \mathbb{C} & \mathrm{USp}(4) & \mathbb{R}
\end{array}
$$

There are 52 distinct Galois types of abelian surfaces.

The proof uses the algebraic Sato-Tate group of Banaszak and Kedlaya, which, for $g \leq 3$, uniquely determines $\mathrm{ST}_{A}$.

## Searching for curves

We surveyed the $\bar{L}$-polynomial distributions of genus 2 curves

$$
\begin{gathered}
y^{2}=x^{5}+c_{4} x^{4}+c_{3} x^{3}+c_{2} x^{2}+c_{1} x+c_{0}, \\
y^{2}=x^{6}+c_{5} x^{5}+c_{4} x^{4}+c_{3} x^{3}+c_{2} x^{2}+c_{1} x+c_{0}
\end{gathered}
$$

with integer coefficients $\left|c_{i}\right| \leq 128$, over $2^{48}$ curves.
We found over 10 million non-isogenous curves with exceptional distributions, including at least 3 apparent matches for all of our target Sato-Tate groups.
Representative examples were computed to high precision $N=2^{30}$.
For each example, the field $K$ was then determined, allowing the Galois type, and hence the Sato-Tate group, to be provably identified.

## Exhibiting Sato-Tate groups of abelian surfaces

Remarkably, the 34 Sato-Tate groups that can arise for an abelian surface over $\mathbb{Q}$ can all be realized via Jacobians of genus 2 curves.

By extending the base field from $\mathbb{Q}$ to a suitable subfield $k$ of $K$, we can restrict $G / G^{0} \simeq \operatorname{Gal}(K / k)$ to any normal subgroup of $\operatorname{Gal}(K / k)$ (this does not change the identity component $G^{0}$ ).

This allows us to realize all 52 Sato-Tate groups using 34 curves.
In fact, these 52 Sato-Tate groups can be realized using just 9 hyperelliptic curves over varying base fields.

Genus 2 curves realizing Sato-Tate groups with $G^{0}=\mathrm{U}(1)$

| CRT (Schoof-Pila) | $\log ^{5} p$ | $\log ^{8} p$ | $\log ^{12} p$ |

## An average polynomial-time algorithm

All of the methods above perform separate computations for each $p$. But we want to compute $L_{p}(T)$ for all good $p \leq N$ using reductions of the same curve in each case.

## An average polynomial-time algorithm

All of the methods above perform separate computations for each $p$. But we want to compute $L_{p}(T)$ for all good $p \leq N$ using reductions of the same curve in each case.

## Theorem (Harvey 2012)

There exists a deterministic algorithm that, given a hyperelliptic curve $y^{2}=f(x)$ of genus $g$ with a rational Weierstrass point and an integer $N$, computes $L_{p}(T)$ for all good primes $p \leq N$ in time

$$
O\left(g^{8+\epsilon} N \log ^{3+\epsilon} N\right),
$$

assuming the coefficients of $f \in \mathbb{Z}[x]$ have size bounded by $O(\log N)$.
Average time is $O\left(g^{8+\epsilon} \log ^{4+\epsilon} N\right)$ per prime, polynomial in $g$ and $\log p$. Recently generalized to arbitrary arithmetic schemes (in principle).
